Introduction to Artificial Intelligence

G. Lakemeyer

Winter Term 2016/17

Games

Games like chess have been studied in AI since the 50-ies.

They are a special variant of search problems.

The states are usually accessible.

The actions are the possible moves of a player.

Complication: More than 1 actor.

From one player's point of view, his or her actions have uncertain outcomes, since the reaction of the opponent is usually not foreseeable.

In this sense games belong to the class of contingency problems (uncertain knowledge of action effects).

Note: The opponent usually chooses actions to do maximal damage.

AI/WS-2016/17 2 / 21

What Makes Games Interesting

Problem: Almost all interesting games are unsolvable in practice.

Chess:

Each player has about 50 moves with about 35 actions per move, i.e. there are about 35¹⁰⁰ nodes in the search tree (with "only" 10⁴⁰ legal chess positions).

Good game programs have the following features:

- a) Early pruning of useless sub-trees.
- b) good evaluation function of states without doing a complete search.

AI/WS-2016/17 3 / 21

2-Person Games – Some Terminology

Players: MAX and MIN with MAX doing the first move.

Initial state: e.g. initial board position, assignment of MAX and MIN.

Operators: legal moves.

Terminal test: when a game ends.

Terminal state game over.

gives a numeric value to the outcome of a game; often **Utility function**

simply +1 (win), -1 (loss), 0 (draw). Backgammon has (payoff):

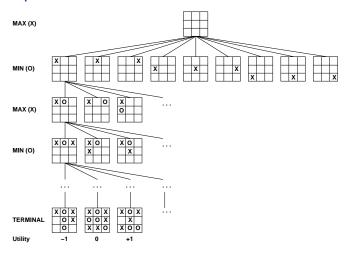

a range between +192 and -192.

in contrast to regular search, MAX needs to find a path Strategy:

which leads to a winning terminal state for every possi-

ble reaction of MIN.

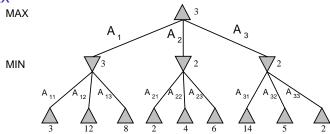

An Example: Tic-Tac-Toe

Each level of the search tree (also called game tree) is labelled with the player whose turn it is (MAX and MIN levels). When the complete game tree can be generated, the optimal strategy for MAX can be computed.

AI/WS-2016/17 5 / 21

Minimax

- Generate a complete game tree.
- Apply utility function to each terminal state.
- Starting from the terminal states, calculate the values for the parent node as follows:
 - If the parent node is at a MIN level, then assign it the minimum of the values of the children.
 - If the parent node is at a MAX level, then assign it the maximum of the values of the children.
 - Then at the root MAX chooses the action which leads to the child with maximum utility (Minimax decision).

Note: Minimax assumes that MIN plays perfectly rational, i.e. always chooses the optimal move.

AI/WS-2016/17 6 / 21

Minimax-Algorithm

```
function MINIMAX-DECISION(game) returns an operator
```

for each op in Operators[game] do

 $VALUE[op] \leftarrow MINIMAX-VALUE(APPLY(op, game), game)$

end

return the op with the highest VALUE[op]

function MINIMAX-VALUE(state, game) **returns** a utility value

if TERMINAL-TEST[game](state) then

return UTILITY[game](state)

else if MAX is to move in state then

return the highest MINIMAX-VALUE of SUCCESSORS(*state*)

else

return the lowest MINIMAX-VALUE of SUCCESSORS(state)

AI/WS-2016/17 7 / 21

Evaluation Functions

When the search space is large, the game tree can only be generated up to a certain depth.

Minimax works then as well. Simply replace TERMINAL-TEST by CUT-OFF-TEST and the utility function UTILITY by the evaluation function EVAL.

The trick is then to correctly evaluate the goodness of the leaves.

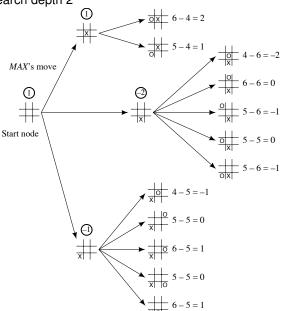

Simple criteria for chess:

- Material value: pawn = 1, knight = 3, bishop = 3, rook = 5, queen = 9.
- Other features: safety of the king, good pawn structure.
- Rule of thumb: 3-point advantage = certain victory.

AI/WS-2016/17 8 / 21

Example: Tic-Tac-Toe (1)

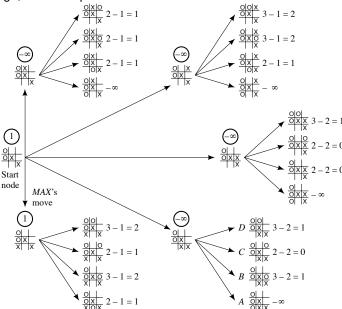

First stage, search depth 2

AI/WS-2016/17

Example: Tic-Tac-Toe (2)

Final stage, search depth 2

AI/WS-2016/17

Form of Evaluation Functions

The choice of an evaluation function is critical.

It should be easy to compute and accurately reflect the chance of winning.

Chance of winning for a given material value means the probability to win averaged over all positions with the same material value.

Usually evaluation functions are weighted linear functions:

$$W_1 f_1 + W_2 f_2 + \ldots + W_n f_n$$

(E.g. MAX = White: $w_1 = 3$, f_1 = number of white knights on the board.)

Assumption: The criteria are independent of each other. (Simplification)

AI/WS-2016/17 11 / 2*

When to Cut Off Search?

Cut-off only in quiescent states, i.e. those which do not lead to dramatic subsequent changes, since the evaluation function is otherwise misleading.

Example:

(a) White to move Fairly even

(b) Black to move White slightly better

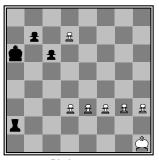

(c) White to move Black winning

White about to lose

Horizon Problem

Black to move

- Black has a slight advantage in material value;
- black loses the game eventually (pawn turns into a queen eventually);
- fixed depth search may not detect this since the "disaster" can be pushed over the horizon.

Alpha-Beta Search Algorithm

```
function MAX-VALUE(state, game, \alpha, \beta) returns the minimax value of state
  inputs: state, current state in game
            game, game description
            \alpha, the best score for MAX along the path to state
            \beta, the best score for MIN along the path to state
  if CUTOFF-TEST(state) then return EVAL(state)
  for each s in SUCCESSORS(state) do
       \alpha \leftarrow \text{MAX}(\alpha, \text{MIN-VALUE}(s, game, \alpha, \beta))
       if \alpha > \beta then return \beta
  end
  return \alpha
function MIN-VALUE(state, game, \alpha, \beta) returns the minimax value of state
  if CUTOFF-TEST(state) then return EVAL(state)
  for each s in SUCCESSORS(state) do
       \beta \leftarrow \text{MIN}(\beta, \text{MAX-VALUE}(s, game, \alpha, \beta))
       if \beta < \alpha then return \alpha
  end
  return \beta
```

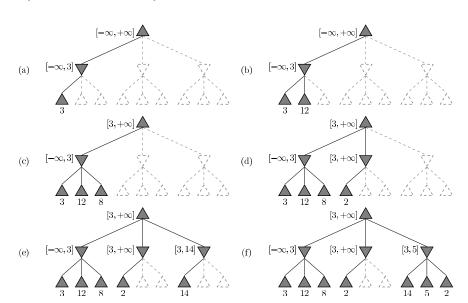

Initialization: $\alpha=-\infty,\,\beta=+\infty.$ Max-Value is applied to nodes at MAX levels, Min-Value at MIN levels.

AI/WS-2016/17 15 / 21

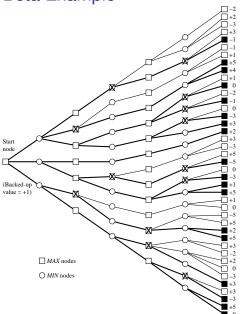

Alpha-Beta Search Algorithm Version 2

```
function ALPHA-BETA-SEARCH(state) returns an action
  inputs: state, current state in game
  v \leftarrow \text{MAX-VALUE}(state, -\infty, +\infty)
  return the action in SUCCESSORS(state) with value v
function MAX-VALUE(state, \alpha, \beta) returns a utility value
  inputs: state, current state in game
            \alpha, the value of the best alternative for MAX along the path to state
            \beta, the value of the best alternative for MIN along the path to state
  if TERMINAL-TEST(state) then return UTILITY(state)
   n \leftarrow -\infty
  for a, s in Successors(state) do
     v \leftarrow \text{MAX}(v, \text{MIN-VALUE}(s, \alpha, \beta))
     if v > \beta then return v
     \alpha \leftarrow \text{Max}(\alpha, v)
  return v
function MIN-VALUE(state, \alpha, \beta) returns a utility value
  inputs: state, current state in game
            \alpha, the value of the best alternative for MAX along the path to state
           \beta, the value of the best alternative for MIN along the path to state
  if TERMINAL-TEST(state) then return UTILITY(state)
  v \leftarrow +\infty
  for a, s in SUCCESSORS(state) do
     v \leftarrow \text{MIN}(v, \text{MAX-VALUE}(s, \alpha, \beta))
     if v \leq \alpha then return v
     \beta \leftarrow \text{MIN}(\beta, v)
  return v
```
